

Abstract

Methods and systems are directed to dynamically mirroring a connection between network devices. Mirroring is managed by forwarding a packet between a first network device and a second network device. In one method, the first network device
5 receives the packet from a client and communicates the packet to the second network device. A forwarding device, pre-determined from the first and second network devices, forwards the packet to a server. The first network device receives a response from the server, and communicates it to the second network device. The forwarding device forwards the response packet to the client. In one configuration, the first network device
10 and forwarding device is an active device, and the second network device is a standby device. In another configuration, the first network device is a standby device, and the second network device and forwarding device is an active device.
